

An Alternative Proton Source

Dave McGinnis April 25, 2005

Motivation

- Develop an alternative plan to provide high intensity proton beams for the neutrino program beyond 2010 should budgets and approvals for the planned projects fail to materialize.
- The proposal needs to have the following important features
 - > It must be inexpensive (< \$100M or so)
 - > It must be completed quickly (before 2012)
 - > It should not shutoff the collider complex or the neutrino program for an extended period of time.
- These goals can be accomplished only if:
 - > It uses the present Fermilab infrastructure (tunnel enclosures, service buildings, power, utilities, etc.)
 - The project is staged

Concept

- This proposal will only discuss producing 8 GeV protons
 - Acceleration in the Main Injector and MI-RF upgrades are treated in the present Proton Plan
 - Also the present Proton Plan is developing the concept to deal with the vulnerability of RF power tubes in the present Linac

Concept

- The cancellation of the BTeV project eliminates the need to produce antiprotons at Fermilab beyond 2009-2010,
- The present antiproton production complex can be converted into a multi-stage proton accumulator for injection into the Main Injector.
 - > Debuncher -> Wide Aperture Booster
 - > Accumulator -> Momentum Stacker
 - > Recycler -> Box Car Stacker

Project Staging

- Because the concept uses existing infrastructure the performance can be broken into stages
- Project staging has the important benefit of providing
 - > a fraction of the total performance
 - > at a fraction of the total cost
- The schedule for each stage is driven by physics need and funding availability

Stages of the Present Proton Plan

- Stage 0 Present Booster -> Main Injector
 - > 6.5×10¹⁶ pph
 - > 220kW 120 GeV Beam
 - > 1.1x10¹⁶ pph BNB
- Stage 1 Proton Plan Booster -> Main Injector (>2008)
 - > 13.6x10¹⁶ pph
 - > 370kW 120 GeV Beam
 - > 5.1x10¹⁶ pph BNB
- Stage 2 Proton Plan Booster -> Recycler -> Main Injector
 - > 13.6x10¹⁶ pph
 - > 725kW 120 GeV Beam

New Stages for the Multi-Stage Proton Accumulator

- Stage 3 Proton Plan Booster -> Present Booster Aperture
 Upgrade -> Accumulator -> Recycler -> Main Injector
 - > 21.6x10¹⁶ pph
 - > 1150kW 120 GeV Beam
- Stage 4 Proton Plan Booster -> New Booster -> Accumulator
 -> Recycler -> Main Injector
 - > 43.2x10¹⁶ pph
 - > 2300kW 120 GeV Beam
 - > Option A
 - 56.8x10¹⁶ pph
 - 2300kW 120 GeV Beam
 - 13.6x10¹⁶ pph BNB
 - Option B
 - 64.8x10¹⁶ pph
 - · 2300kW 120 GeV Beam
 - 21.6x10¹⁶ pph BNB

Multi-stage Proton Accumulator Scheme

- Stages 0-2 are covered in the present Proton Plan
- The rest of this presentation will discuss Stages 3 and 4

Multi-stage Proton Accumulator Scheme

- Keep the present 400 MeV Linac
- Accelerate in a Wide Aperture Booster
 - > Stage 3 Upgrade the present Booster to run at 6×10^{13} protons/sec
 - Low intensity per pulse 4.0x10¹² protons/pulse
 - Fast repetition rate 15 Hz
 - > Stage 4 New Booster in place of the Debuncher ring to run at 1.2×10^{14} protons/sec
 - High intensity per pulse 8x10¹² protons/pulse
 - Fast repetition rate 15 Hz

Multi-stage Proton Accumulator Scheme

Momentum stack in the Accumulator

- > Inject in a newly accelerated Booster batch every 67 mS onto the high momentum orbit of the Accumulator
- > Decelerate new batch towards core orbit and merge with existing beam
- > Momentum stack 3-4 Booster batches
- > Extract a single Accumulator batch
 - Every 200 270 mS
 - At an intensity of 3-4x a single Booster batch
- Box Car Stack in the Recycler
 - > Load in a new Accumulator batch every 200-270mS
 - Place six Accumulator batches sequentially around the Recycler
- Load the Main Injector in a single turn

Multi-stage Proton Accumulator Production Cycle

Acceleration in a Wide Aperture Booster

- Using the Accumulator as a proton accumulator reduces the peak intensity requirement in the Booster
- Results in a smaller required aperture
 - > Smaller space charge tune shift
 - > Reduced requirements on acceleration efficiency

Scaling

- Use present Booster performance to scale for acceptable beam loss
- > Use PD2 Design report for scaled cost estimate

Scaling Laws

Compare designs with the same space charge tune shift

$$\epsilon_{\rm n} \propto \frac{N_{\rm inj}}{\beta \gamma^2 \Delta \nu}$$

 Amount of beam power lost per pulse is inversely proportional to the repetition rate

$$P_{L} = J_{L}R$$

 The transverse acceptance is inversely proportional to the amount of beam loss in the "tails" of the beam

$$A_n \propto -\varepsilon_n \ln \left(\frac{N_{inj} - N_{ext}}{2N_{inj}} \right)$$

- The half-aperture of the magnets is proportional to
 - > The transverse acceptance,
 - > The momentum acceptance
 - > The closed orbit displacement

$$\Delta x = \sqrt{\frac{A_n}{\beta \gamma} \beta_{max}} + \frac{\Delta p}{p} D_{max} + c.o.d.$$

Present Booster Performance

Wide Aperture Booster - Stage 3

- Upgrade the present Booster to run at 6x10¹³ protons/sec
 - > Would be 1.1MW at 120 GeV
 - ➤ Low intensity per pulse 4.0x10¹² protons/pulse
 - > Fast repetition rate 15 Hz
- Acceptable Losses
 - > Present
 - 3.35×10¹² protons/pulse
 - 5.46Hz
 - 83% efficiency
 - 70 Joules/pulse lost
 - ➤ Stage 3
 - 4.0x10¹² protons/pulse
 - 15Hz
 - 95% efficiency
 - 25 Joules/pulse lost

Stage 3 Wide Aperture Booster Components

- Move the notcher from the Booster to the front end of the Linac (< \$100k)
 - Using momentum stacking in the Accumulator eliminates the need for cogging in the Booster
 - Prior to injection into the Accumulator, the injection orbit of the Accumulator is empty
 - The Accumulator injection system can be phase-locked to the Booster which eliminates the need for cogging in the Booster
 - The Booster notch can be made in the Linac
 - > Need to upgrade Linac chopper power supply and controls
 - > Saves 24 Joules/pulse at 4.0x1012 protons/pulse

Stage 3 Wide Aperture Booster Components

Extraction Septum Upgrades

- > Collimators are presently used to shield small apertures at the extraction septa
- > Remove Long 13 extraction septum (~ \$100k)
 - Place a low intensity dump in the MI-8 line for short batches
 - Use the Long 12 kicker for more extraction kick at Long 3
- Long 3 Pulsed extraction 3 bump (~\$1M)
 - Replace 400 MeV doglegs with pulsed 8 GeV 3 Bump
- > Pull collimators out to larger aperture
- > Saves 13 Joules/pulse at 4.0x1012 protons/pulse

Stage 3 Wide Aperture Booster Components

Aperture Upgrade

- Booster RF Cavity Upgrade (~ \$25M)
 - Build the RF cavities for the new Booster (Stage 4)
 - Install the new cavities in the old Booster
 - Operate the cavities in old Booster until new Booster is ready to be installed and remove and install the new RF cavities in the new Booster
 - Increase the RF cavity aperture by 75% (2.25" -> 3")
 - Cavities incorporate
 - Passive HOM dampers
 - Reliable Power electronics
 - Provide 15 Hz capability
- Proton Plan (Stage 1)
 - · Alignment \$0.09M
 - · Gamma-t jump \$0.1M
 - Ramped correctors \$2.1M
 - OR-BUMP \$0.7M
 - Also provides 15 Hz capability
 - 30 Hz harmonic \$1.8M
- ➤ Need to save 7 Joules/pulse at 4.0×10¹² protons/pulse

Stage 3 Cost Guess (in k\$)

D Aperture Height	1.9	2.0	2.0	3.0	4.2	in

AP-4 Line

 The old Booster is connected to the new Booster via a re-built AP4 Line

The new AP4 line is about 240 meters in length

Compared to the 600
 MeV line of PD2 which is 250 meters in length

Magnets 1 M\$

Civil Construction 1.8 M\$

Features of the New Booster

- Ramps from 400 MeV to 8 GeV
- Fast cycling (15 Hz)
- Large aperture
- Separated function magnets.
- Dual harmonic power system for an asymmetric acceleration ramp
- Does not go through transition
- Zero dispersion at the RF cavities
- Modern RF cavity design with higher order mode dampers.
 - > Install the new cavities in the old Booster during Stage 3
 - > Operate the cavities in old Booster until new Booster is ready to be installed and remove and install the new RF cavities in the new Booster

Stage 4 Triangular Lattice

Stage 4 Triangular Lattice

- Triangular shape to fit to the Debuncher footprint
- No transition crossing ($\gamma_t = 18.1$)
- Zero dispersion straights
- Simple: 1 type of dipole, 1 type of quad (QF and QD same length)
- Doublet lattice, 90° phase advance per cell
- 3 cells per module, with missing dipole in the mid-cell, 270° phase advance per module
- 4 modules per arc, 6π phase advance per arc
- No need for dispersion suppressor
- Plenty of free space: 24 x 7 m
- Low beta-function (15 m) and dispersion (2.3 m)
- Good optical properties (large dynamic aperture, weak dependence of lattice functions on amplitude and dp/p)

AP-3 Line Modification

 The AP3 line needs to be connected to the MI-8 line

The modification is about100 meters in length

- Magnets 0.8 M\$
- Civil Construction 1.1 M\$
- Compared to the 8 GeV line of PD2 which is 420 meters in length
 - · Magnets 1.9 M\$
 - Civil Construction 2.2 M\$

Cost Comparison Between Stage 4 and PD2

- Reuse the pbar tunnel
 - > Saving \$43M in civil
 - > However include \$3M for radiation shielding
- Reduce magnet aperture from 4" x 6" to 3" x 5"
 - > Saving \$20M in magnet and power supply cost.
- Use new type of beam pipe
 - > Saving \$1M in vacuum
- Reuse utilities
 - > Existing in Pbar Tunnel
 - > Lower beam power.
 - > saving \$4.4M
- Reuse controls
 - > saving \$2M
- Do not need foil changer,
 - > saving \$0.15M.
- The new cost estimate is about \$50M,
 - > The RF (~25M\$) is purchased in Stage 3

Stage 4 Cost Guess (in k\$)

Stage 4		50,200
Magnets	17,000	
Power supplies	16,000	
RF Installation	200	
Vacuum	5,000	
Collimators	300	
AP4 Line 400 MeV	/ Magnets 1000	
Injection system	900	
Extraction system	2,100	
Instrumentation	2,400	
Controls	500	
Utilities	500	
Installation	1,300	
Shielding	3,000	

Stage 4 Booster vs BNL AGS Booster

	Stage 4	AGS Booster
Circumference (m)	505	201
Injection (MeV)	400	200
Extraction (GeV)	8	1.5
Rep rate (Hz)	15	7.5
Total dipoles	$24 \times 5.2 \text{ m} = 124.8 \text{ m}$	$36 \times 2.4 \text{ m} = 86.4 \text{ m}$
Total quads	$96 \times 1.24 \text{ m} = 119 \text{ m}$	$48 \times 0.5 \text{ m} = 24 \text{ m}$
Beam pipe aperture	$3 \text{ in} \times 5 \text{ in}$	$2.8 \text{ in} \times 5.9 \text{ in}$
Max β function (m)	14.8 / 15.2	13.9 / 13.7
Max dispersion (m)	2.3	2.9
Transition γ	18.1	4.79
Beam intensity	7×10^{12}	2×10^{13}
Year constructed	TBD	1991
Construction cost	\$75M (estimated)	\$32M (1991)
Civil cost included?	No	Yes

- Adjust \$32M in 1991 for 14 years of 4% of inflation = \$55M
- Scale the cost as the length in magnets = \$122M
- Remove civil construction = \$122M \$43M = \$79M

Momentum Stacking in the Accumulator

- After acceleration in the Booster the beam will be transferred to the Accumulator ring.
- Using the Accumulator as a proton accumulator reduces the peak intensity requirement in the Booster
- Results in a smaller required aperture for the Booster
 - > Smaller space charge tune shift
 - > Reduced requirements on acceleration efficiency
- The Accumulator was designed for momentum stacking
 - ➤ Large momentum aperture ~ 84 x 2.8 eV-Sec
 - > Injection kickers are located in 9m of dispersion
 - > Injection kickers do not affect core beam

Advantages of Momentum Stacking

Transient Beam Loading

- Slip stacking or barrier bucket stacking requires manipulating intense beams wit low RF voltages in a mostly empty circumference
- > In momentum stacking, the circumference is always uniformly loaded

Speed of process

> Injected beam can be decelerated quickly towards the core beam

Longitudinal emittance dilution

> The core beam can be debunched during stacking process reducing the amount of "white spaces"

Cogging in the Booster

- Prior to injection into the Accumulator, the injection orbit of the Accumulator is empty
- > The Accumulator injection system can be phase-locked to the Booster which eliminates the need for cogging in the Booster
- > The Booster notch can be made in the Linac

Mechanics of Momentum Stacking

- Inject in a newly accelerated Booster batch every 67 mS onto the high momentum orbit of the Accumulator
- The freshly injected batch is decelerated towards the core orbit where it is merged and debunched into the core orbit
- Momentum stack 3-4 Booster batches
 - > The longitudinal emittance of a batch at 8 GeV from the present Booster is 84x0.1eV-sec
 - The present momentum aperture of the Main Injector is 0.5 eV-Sec for a 53 MHz bunch
 - Will need at γ_t jump system in the Main Injector (~ \$0.5M)

Extraction From the Accumulator

- After 3-4 batches have been stacked begin preparing to extract all the beam from the Accumulator to the Recycler
- Re-bunch the entire stacked beam at h=4 in the Accumulator (2.5 MHz)
 - 2.5 MHz would provide a large gap between buckets which could accommodate kicker rise time
 - Could consider higher harmonic bunching (h=21, RF frequency = 13.2MHz)
 - Keep the momentum spread low
 - · Keep synchrotron frequency high
- Other Schemes
 - > Re-bunching at 53 MHz would require at gap placed in the beam for kicker rise time
 - Speed and voltage of a barrier bucket is a concern
 - Preserve gap from injection by never debunching the Booster batches and slip stacking the gaps
 - Revolution frequencies are close so slipping would be slow
 - Emittance dilution is a concern

Extraction From the Accumulator

- Accelerate the beam to the extraction orbit
 - > Phase lock to the Recycler
 - If the accumulator is at η =0.023, the revolution frequency of the Recycler is harmonically related to the revolution frequency of the extraction orbit of the Accumulator
 - Kick the beam into the AP3 line using the Accumulator high dispersion extraction kickers
 - Might have to extend the momentum range of the extraction kicker
 - Place an extra kicker where the present 4-8 GHz momentum cooling system is presently located

Box Car Stacking in the Recycler

- After 3-4 booster batches have been momentum stacked in the Accumulator, the beam would be transferred to the Recycler.
 - > 2.5 MHz synchronous transfer
 - > Accumulator phase locked to the Recycler
- The Accumulator is 1/7 of the Recycler's circumference
- Boxcar stack six of the Accumulator batches (which contain 3-4 of the Booster batches), leaving 1/7 of the Recycler ring for an abort gap.
- After 6 Accumulator batches have been stacked into the Recycler do a 2.5 MHz synchronous transfer to the Main Injector
- In the Main Injector
 - perform a 2.5 MHz bunch rotation to reduce the momentum spread
 - > Re-capture in 53 MHz buckets for acceleration.

Booster Neutrino Beamline (BNB) Option

- After Stage 4 is complete, the old Booster is abandoned
- The present Linac can support pulse lengths in excess of 50 μS
 - \triangleright A 40mA Linac beam pulse for 50 μ S has 12.4x10¹² particles
- From a single Linac pulse, a chopper placed in the 400 MeV line would be able to send
 - > 8.2×10¹² protons to the new booster
 - \rightarrow 4.2x10¹² protons to the old booster.
- This would require an RF acceleration system in both Boosters.

Booster Neutrino Beamline (BNB) Option Option

- An RF acceleration system in both Boosters.
 - > Option A:
 - Move the RF system built for Stage 3 into the new booster
 - Re-install the old RF system into old Booster
 - · Comments
 - Inexpensive
 - Keeps BNB at 13.6x10¹⁶ protons/hour
 - > Option B:
 - Keep the RF system built for Stage 3 in the old Booster
 - Build a new set of cavities for the new Booster.
 - · Comments
 - Expensive ~ \$25M
 - Gets BNB to 21.6x10¹⁶ protons/hour
 - Keeping the old Booster running while installing the new Booster makes the transition between Stage 3 to Stage 4 easier

Summary

- The present antiproton production complex can be converted into a multi-stage proton accumulator
 - > That supplies enough protons for a 1.1 MW 120 GeV beam for a cost of about \$40M (\$5M of which is already funded in the present Proton Plan)
 - > That can be upgraded to provide enough protons for a 2.3 MW 120 GeV beam for an additional cost of about \$50M
- Because the concept uses existing infrastructure the performance can be broken into stages
 - > Project staging has the important benefit of providing
 - · a fraction of the total performance
 - at a fraction of the total cost
 - The schedule for each stage is driven by physics need and funding availability
- Integrating the present Booster into this scheme could in addition provide 8 GeV protons in 1.6 μS bursts at a rate of 14-21x10¹⁶ protons/hour for a Booster Neutrino Beam (BNB)

Things To Do

- Get cost estimate for Booster RF upgrade
- Lattice design for the new Booster
- Layout of AP3 modification and AP4 line
- Simulate momentum stacking
- Simulate extraction from the Accumulator
